Discussions

Machine Problem 2: Hadoop MapReduce

1 Overview

Welcome to the Hadoop MapReduce programming assignment. You may choose to complete this machine problem in **either** Java or Python. Please choose the language that you prefer. It is highly recommended that you practice the **Tutorial**: **Docker installation** and **Tutorial**: **Introduction to Hadoop MapReduce** (under week 4) before beginning this assignment.

2 General Requirements

Please note that our grader runs on a docker container and is **NOT connected to the internet**. Therefore, **no additional libraries are allowed** for this assignment. Also, you will **NOT be allowed to create any file or folder outside the current folder** (that is, you can only create files and folders in the folder that your solutions are in).

3 Sorting

When you are to select top N items in a list, sorting is implicitly needed. Use the following steps to sort:

- 1. Sort the list ASCENDING based on **Firstly** <u>count</u> then **Secondly** on the value. If the value is string, sort lexicographically.
- 2. Select the bottom N items in the sorted list as Top items.

There is an implementation of this logic in the the third example of the Hadoop MapReduce Tutorial.

Q

For example, to select top 5 items in the list {"A": 100, "B": 99, "C":98, "D": 97, "E": 96, "F": 96, "G":90}, first sort the items ASCENDING:

"G":90

<u>"E"</u>: 96

<u>"F"</u>: 96

"D": 97

"C":98

"B": 99

"A": 100

Then, the bottom 5 items are **A, B, C, D, F**.

Another example, to select 5 top items in the list {"43": 100, "12": 99, "44":98, "12": 97, "1": 96, "100": 96, "99":90}

"99":90

<u>"1"</u>: 96

<u>"100"</u>: 96

"12": 97

"44":98

"12": 99

"43": 100

Then, the bottom 5 items are 43, 12, 44, 12, 100.

Java submission

If you choose to do this assignment in Python, skip this part and go to "Python** submission" part below.

1 Requirements

This assignment will be graded based on JDK 8

C

2 Procedures

Step 1: Run the provided sample Docker image (please follow "Tutorial: Docker installation" in week 4)

\$ docker run -it sample_image.v1 bin/bash
root@f9922c3fe307:/#

Step 2: Download the project files

1 # git clone https://github.com/UIUC-public/MP2_java.git

step 3: Change the current folder to

1 # cd MP2_java/

step 4: Finish the exercises by editing the provided templates files. All you need to do is complete the parts marked with **TODO**. Please note that you are **NOT allowed to import any additional libraries.**

- Each exercise has a Java code template. All you must do is edit this file.
- Each exercise should be implemented in one file only. Multiple file implementation is not allowed.
- The code should be compiled and run on the sample Docker image.
- For partial credit: Only submit the files related to the exercise in a zip format (MP2.zip)
- If you need to create a new path in the **run** function, please always use **Path tmpPath** = **new Path("./tmp")**. Creating any other path may lead to Hadoop jar Error.

More information about these exercises is provided in the next section.

step 5: After you are done with the assignments, put all your 5 java files (TopTitles.java, TopTitlesStatistics.java, OrphanPages.java, TopPolularLinks.java, PopularityLeague.java) into a folder named as "MP2". Compress your "MP2" folder into a .zip file named as "MP2.zip". Submit your "MP2.zip".

Exercise A: **Top Titles**

In this exercise, you are going to implement a counter for words in Wikipedia titles and an application to find the top words used in these titles. To make the implementation easier, we have provided a boilerplate for this exercise in the following file: **TopTitles.java**

All you need to do is make the necessary changes to parts that are marked with **TODO**.

Your application takes a huge list of Wikipedia titles (one in each line) as an input and first tokenizes them using <u>provided delimiters</u>, after that make the tokens <u>lowercased</u>, then removes common words from the <u>provided stopwords</u>. Next, your application selects top **10** words, and finally, saves the count for them in the output. <u>Use the method in section 3</u> <u>Sorting to select top words</u>.

(optional) In TopTitles.java, you will find a class named as "TitleCountMap" and a class named as "TitleCountReduce". To complete these two classes, you may find the "TitleCount.java" template helpful. In this part, you should tokenize Wikipedia titles, make the tokens lowercased, remove common words, and save the count for all words in the output. You can test your TitleCount.java with:

```
1 # mkdir ./TitleCountClasses
2 # javac -cp $(hadoop classpath) TitleCount.java -d
    TitleCountClasses
3 # jar -cvf TitleCount.jar -C TitleCountClasses/ ./
4 # hadoop jar TitleCount.jar TitleCount -D stopwords=stopwords.txt
    -D delimiters=delimiters.txt dataset/titles ./temp-output
```

The order of output is NOT important. Here is **a part** of the sample output:

```
list 1948
      1684
de
      1077
new
            1065
school
            1020
county
state 940
john 936
disambiguation
                  893
station
            800
route 771
```

Because of the possible problems with special characters, we will not run TitleCount.java or check the output for this part. You don't need to submit this file. The template is there only to help you to understand TitleCountMap class and TitleCountReduce class in **TopTitles.java**.

The following is the sample command we will use to run the application:

```
1 # mkdir ./TopTitlesClasses
2 # javac -cp $(hadoop classpath) TopTitles java -d TopTitlesClasses
3 # jar -cvf TopTitles.jar -C TopTitlesClasses/ ./
4 # hadoop jar TopTitles.jar TopTitles -D stopwords=stopwords.txt -D delimiters=delimiters.txt dataset/titles ./A-output
```

If you want to check your output, run:

```
1 # cat A-output/part-r-00000
```

Here is the output of an application that selects top **5** words:

county	1020
school	1065
new	1077
de	1684
list	1948

The order of lines matters. TextArrayWritter and Pair classes are included in the template to optionally help you with your implementation.

Exercise B: **Top Title Statistics**

In this exercise, you are going to implement an application to find some statistics about the top words used in Wikipedia titles. To make the implementation easier, we have provided a boilerplate for this exercise in the following file: **TopTitleStatistics.java**

All you need to do is make the necessary changes to parts that are marked with **TODO**.

Your application takes a huge list of Wikipedia titles (one in each line) as an input and first tokenizes them using provided delimiters, after that make the tokens <u>lowercased</u>, then removes common words from the provided stopwords list. Next, selects top **10** words. <u>Use the method in section 3 Sorting to select top words</u>.

Finally, the application saves the following statistics about the top words in the output: "Mean" count, "Sum" of all counts, "Minimum" and "Maximum" of counts, and "Variance" of the counts. All values should be **floored** to be an integer. For the sake of simplicity, simply use Integer in all calculations.

The following is the sample command we will use to run the application:

- 2 # javac -cp \$(hadoop classpath) TonTitleStatistics.java -d TopTitleStatisticsClasses
- 3 # jar -cvf TopTitleStatistics.jar -C TopTitleStatisticsClasses/ ./
- 4 # hadoop jar TopTitleStatistics.jar TopTitleStatistics -D stopwords=stopwords.txt -D delimiters=delimiters.txt dataset/titles ./B-output

If you want to check your output, run:

```
1 # cat B-output/part-r-00000
```

Here is the output of an application that selects top **5** words:

Mean	1358
Sum	6794
Min	1020
Max	1948
Var	146686

The order of lines matters. TextArrayWritter and Pair classes are included in the template to optionally help you with your implementation.

Exercise C: Orphan Pages

In this exercise, you are going to implement an application to find orphan pages in Wikipedia. To make the implementation easier, we have provided a boilerplate for this exercise in the following file: OrphanPages.java

All you need to do is make the necessary changes to parts that are marked with **TODO**.

Your application takes a huge list of Wikipedia links (not Wikipedia titles any more) as an input. All pages are represented by their ID numbers. Each line starts with a page ID, which is followed by a list of all the pages that the ID has a link to. The following is a sample line in the input:

2: 3 747213 1664968 1691047 4095634 5535664

In this sample, page 2 has links to page 3, 747213, and so on. Note that links are not necessarily two-way. The application should save the IDs of orphan pages in the output. Orphan pages are pages to which no other pages link.

The following is the sample command we will use to run the application:

	•		

- 1 # mkdir ./OrphanPagesClasses
- 2 # javac -cp \$(hadoop classpath) OrphanPages.java -d
 OrphanPagesClasses
- 3 # jar -cvf OrphanPages.jar -C OrphanPagesClasses/ ./
- 4 # hadoop jar OrphanPages.jar OrphanPages dataset/links ./C-output

If you want to check your output, run:

```
1 # cat C-output/part-r-00000
```

If you want to check a **part** of your output, run:

```
1 # head C-output/part-r-00000
```

Here is a part of the output for this application:

```
2
14
24
51
68
83
103
107
149
```

The order of lines matters. All values are integers.

Exercise D: Top Popular Links

In this exercise, you are going to implement an application to find the most popular pages in Wikipedia. To make the implementation easier, we have provided a boilerplate for this exercise in the following file: **TopPopularLinks.java**

All you need to do is make the necessary changes to parts that are marked with **TODO**.

Your application takes a huge list of Wikipedia links as an input. All pages are represented by their ID numbers. Each line starts with a page ID, which is followed by a list of all the pages that the ID has a link to. The following is a sample line in the input:

2: 3 747213 1664968 1691047 4095634 5535664

In this sample, page 2 has links to page 3, 747213, and so on. Note that links are not necessarily two-way. The application should save the IDs of top 10 popular pages as well as the number of links to them in the output. A page is popular if more pages are linked to it. **Use the method in section 3 Sorting to select top links**.

The following is the sample command we will use to run the application:

- 1 # mkdir ./TopPopularLinksClasses
- 2 # javac -cp \$(hadoop classpath) TopPopularLinks.java -d
 TopPopularLinksClasses
- 3 # jar -cvf TopPopularLinks.jar -C TopPopularLinksClasses/ ./
- 4 # hadoop jar TopPopularLinks.jar TopPopularLinks dataset/links ./D-output

If you want to check your output, run:

```
1 # cat D-output/part-r-00000
```

Here is the output of an application that selects top 5 popular links;

1921890 721 481424 729 84707 1060 5302153 1532 88822 1676

The order of lines matters. All values are integers. IntArrayWritter and Pair classes are included in the template to optionally help you with your implementation.

Exercise E: Popularity League

In this exercise, you are going to implement an application to find the most popular pages in Wikipedia. To make the implementation easier, we have provided a boilerplate for this exercise in the following file: **PopularityLeague.java**

All you need to do is make the necessary changes to parts that are marked with **TODO**.

Your application takes a huge list of Wikipedia links as an input. All pages are represented by their ID numbers. Each line starts with a page ID, which is followed by a list of all the pages that the ID has a link to. The following is a sample line in the input:

2: 3 747213 1664968 1691047 4095634 5535664

In this sample, page 2 has links to page 3, 747213, and so on. Note that links are not necessarily two-way.

The **popularity** of a page is determined by the number of pages in the whole Wikipedia graph that link to that specific page. (Same number as **Exercise D**)

The application also takes a list of page IDs as an input (also called a **league list**). The goal of the application is to calculate the rank of pages in the league using their popularity.

The <u>rank</u> of the page is the number of pages in the <u>league</u> with strictly less (not equal) popularity than the original page.

The following is the sample command we will use to run the application:

- 1 # mkdir ./PopularityLeagueClasses
- 2 # javac -cp \$(hadoop classpath) PopularityLeague.java -d
 PopularityLeagueClasses
- 3 # jar -cvf PopularityLeague.jar -C PopularityLeagueClasses/ ./
- 4 # hadoop jar PopularityLeague.jar PopularityLeague -D league=dataset/league.txt dataset/links ./E-output

If you want to check your output, run:

```
1 # cat E-output/part-r-00000
```

Here is the output with **League**={5300058,3294332,3078798,1804986,2370447,81615,3,1}}:

Here is the output with **League**= {88822,774931,4861926,1650573,66877,5115901,75323,4189215}):

5115901 4 4861926 0 4189215 6

1650573 2

774931

88822

75323

66877

Q

The order matters. Note that we will use a different League file in our test. All values are integers. **IntArrayWriter** class is included in the template to optionally help you with your implementation.

Python submission

**If you choose to do this assignment in Java, skip this part and go to "Java submission" part above

1 Requirements

This assignment will be graded based on Python 2.7

2 Procedures

Step 1: Run the provided Docker image (please follow "Tutorial: Docker installation" in week 4)

\$ docker run -it sample_image.v1 bin/bash
root@f9922c3fe307:/#

Step 2: Download the project files

1 # git clone https://github.com/UIUC-public/MP2_py.git

step 3: Change the current folder to

1 # cd MP2_py/

C

step 4: Finish the exercises by editing the provided templates files. All you need to do is complete the parts marked with **TODO**. Please note that you are **NOT allowed to import any additional libraries.**

- Each exercise has one or more code template. All you must do is edit these files.
- The code will be run on the provided Docker image.
- For partial credit: Only submit the files related to the exercise in a zip format (MP2.zip).
 Example: For part A, only submit TitleCountMapper.py, TitleCountReducer.py,
 TopTitlesMapper.py, TopTitlesReducer.py files to receive a partial credit.

More information about these exercises is provided in the next section.

step 5: After you are done with the assignments, put all your 14 python files (<u>TitleCountMapper.py</u>, <u>TitleCountReducer.py</u>, <u>TopTitlesMapper.py</u>, <u>TopTitlesReducer.py</u>, <u>TopTitlesStatisticsMapper.py</u>, <u>TopTitlesStatisticsReducer.py</u>, <u>OrphanPagesMapper.py</u>, <u>OrphanPagesReducer.py</u>, <u>LinkCountMapper.py</u>, <u>LinkCountReducer.py</u>, <u>TopPolularLinksMapper.py</u>, <u>TopPolularLinksReducer.py</u>, <u>PopularityLeagueMapper.py</u>, <u>PopularityLeagueReducer.py</u>) into a folder named as "**MP2**". Compress your "**MP2**" folder into a .zip file named as "**MP2.zip**". Submit your "**MP2.zip**".

Exercise A: Top Titles

In this exercise, you are going to implement a counter for words in Wikipedia titles and an application to find the top words used in these titles. To make the implementation easier, we have provided a boilerplate for this exercise in the following files: **TitleCountMapper.py**, **TitleCountReducer.py**, **TopTitlesMapper.py**, **TopTitlesReducer.py**

All you need to do is make the necessary changes to parts that are marked with **TODO**.

Your application takes a huge list of Wikipedia titles (one in each line) as an input and first tokenizes them using <u>provided delimiters</u>, after that make the tokens <u>lowercased</u>, then removes common words from the <u>provided stopwords</u>. Next, your application selects top **10** words, and finally, saves the count for them in the output. <u>Use the method in section 3</u> <u>Sorting to select top words</u>.

You should first tokenize Wikipedia titles, make the tokens lowercased, remove common words, and save the count for all words in the output with **TitleCountMapper.py** and **TitleCountReducer.py**.

You can test your output with:

The order of the output is NOT important. Here is **a part** of the output of this:

```
list 1948
de
      1684
      1077
new
school
            1065
            1020
county
state 940
john 936
disambiguation
                  893
station
            800
route 771
```

Because of the possible problems with special characters, we will not check the output for this part. We will only check the top words and their counts.

The following is the sample command we will use to run the application:

```
# hadoop jar /usr/local/hadoop/share/hadoop/tools/lib/hadoop-strea
ming-2.9.0.jar -mapper 'TitleCountMapper.py stopwords.txt
delimiters.txt' -file TitleCountMapper.py -reducer
'TitleCountReducer.py' -file TitleCountReducer.py -input
dataset/titles/ -output ./preA-output_Python
# hadoop jar /usr/local/hadoop/share/hadoop/tools/lib/hadoop-strea
ming-2.9.0.jar -mapper 'TopTitlesMapper.py' -file
TopTitlesMapper.py -reducer 'TopTitlesReducer.py' -file
TopTitlesReducer.py -input ./preA-output_Python/ -output
./A-output_Python
```

If you want to check your output, run:

```
1 # cat A-output_Python/part-00000
```

Here is the output of an application that selects top **5** words:

school

1020 county 1684 list 1948 1077 new

The order of lines matters. Please sort the output (key value) in alphabetic order. Also, make sure the key and value pair in final output are tab separated.

Exercise B: **Top Title Statistics**

1065

In this exercise, you are going to implement an application to find some statistics about the top words used in Wikipedia titles. To make the implementation easier, we have provided a boilerplate for this exercise in the following files: TopTitleStatisticsMapper.py,

TopTitleStatisticsReducer.py

All you need to do is make the necessary changes to parts that are marked with **TODO**.

Your output from Exercise A will be used here. The application saves the following statistics about the top words in the output: "Mean" count, "Sum" of all counts, "Minimum" and "Maximum" of counts, and "Variance" of the counts. All values should be **floored** to be an integer. For the sake of simplicity, simply use Integer in all calculations.

The following is the sample command we will use to run the application:

```
1 # hadoop jar /usr/local/hadoop/share/hadoop/tools/lib/hadoop-strea
   ming-2.9.0.jar -mapper 'TopTitleStatisticsMapper.py' -file
   TopTitleStatisticsMapper.py -reducer
   'TopTitleStatisticsReducer.py' -file TopTitleStatisticsReducer.py
   -input ./A-output_Python/ -output ./B-output_Python
```

If you want to check your output, run:

```
1 # cat B-output_Python/part-00000
```

Here is the output of an application that selects top **5** words:

Sum 6794 Min 1020 Max 1948 Var 146686

Make sure the stats and the corresponding results are tab separated.

Exercise C: Orphan Pages

In this exercise, you are going to implement an application to find orphan pages in Wikipedia. To make the implementation easier, we have provided a boilerplate for this exercise in the following files: **OrphanPagesMapper.py**, **OrphanPagesReducer.py**

All you need to do is make the necessary changes to parts that are marked with **TODO**.

Your application takes a huge list of Wikipedia links (not Wikipedia titles anymore) as an input. All pages are represented by their ID numbers. Each line starts with a page ID, which is followed by a list of all the pages that the ID has a link to. The following is a sample line in the input:

2: 3 747213 1664968 1691047 4095634 5535664

In this sample, page 2 has links to page 3, 747213, and so on. Note that links are not necessarily two-way. The application should save the IDs of orphan pages in the output. Orphan pages are pages to which no other pages link.

The following is the sample command we will use to run the application:

1 # hadoop jar /usr/local/hadoop/share/hadoop/tools/lib/hadoop-strea
ming-2.9.0.jar -mapper 'OrphanPagesMapper.py' -file
OrphanPagesMapper.py -reducer 'OrphanPagesReducer.py' -file
OrphanPagesReducer.py -input dataset/links/ -output
./C-output_Python

If you want to check your output, run:

1 # cat C-output_Python/part-00000

If you want to check a **part** of your output, run:

1 # head C-output_Python/part-00000

Here is a part of the output of this application:

100162

100110

100219

The order of lines matters. Please sort your output (key value) in alphabetic order.

Exercise D: Top Popular Links

In this exercise, you are going to implement an application to find the most popular pages in Wikipedia. To make the implementation easier, we have provided a boilerplate for this exercise in the following files: LinkCountMapper.py, LinkCountReducer.py, TopPopularLinksMapper.py, TopPopularLinksReducer.py

If you have finished Exercise A, LinkCountMapper.py, LinkCountReducer.py should produce output similar to TitleCountMapper.py, TitleCountReducer.py in Exercise A. Instead of printing the count for each title, LinkCountMapper.py and LinkCountReducer.py should output the link count for each page P, or the number of pages are linked to P. Be careful about the format of output produced by LinkCountMapper.py and LinkCountReducer.py., since the output of them is supposed to be the input of TopPopularLinksMapper.py . So if you use tab to separate the page ID and its link count, your TitleCountMapper.py should also consume its input in this way.

All you need to do is make the necessary changes to parts that are marked with **TODO**.

Your application takes a huge list of Wikipedia links as an input. All pages are represented by their ID numbers. Each line starts with a page ID, which is followed by a list of all the pages that the ID has a link to. The following is a sample line in the input:

2: 3 747213 1664968 1691047 4095634 5535664

 \equiv

In this sample, page 2 has links to page 3, 747213, and so on. Note that links are not necessarily two-way. The application should receive of top **10** popular pages as well as the number of links to them in the output. A page is popular if more pages are linked to it.

Use the method in section 3 Sorting to select top links.

The following is the sample command we will use to run the application:

- # hadoop jar /usr/local/hadoop/share/hadoop/tools/lib/hadoop-strea
 ming-2.9.0.jar -mapper 'LinkCountMapper.py' -file
 LinkCountMapper.py -reducer 'LinkCountReducer.py' -file
 LinkCountReducer.py -input dataset/links/ -output
 ./linkCount-output_Python
- # hadoop jar /usr/local/hadoop/share/hadoop/tools/lib/hadoop-strea
 ming-2.9.0.jar -mapper 'TopPopularLinksMapper.py' -file
 TopPopularLinksMapper.py -reducer 'TopPopularLinksReducer.py'
 -file TopPopularLinksReducer.py -input ./linkCount-output_Python
 -output ./D-output_Python

If you want to check your output, run:

```
1 # cat D-output_Python/part-00000
```

Here is the output of an application that selects top **5** popular links:

1921890 721 481424 729 5302153 1532 84707 1060 88822 1676

The order of lines matters. Please sort your output (key value) in alphabetic order. Also, make sure the key and value pair in final output are tab separated.

Exercise E: **Popularity League**

In this exercise, you are going to implement an application to find the most popular pages in Wikipedia. To make the implementation easier, we have provided a boilerplate for this exercise in the following file: **PopularityLeagueMapper.py**, **PopularityLeagueReducer.py**

All you need to do is make the necessary changes to parts that are marked with **TODO**.

Your application takes a huge list of Wikipedia links as an input. All pages are represented by their ID numbers. Each line starts with pages is followed by a list of all the pages that the ID has a link to. The following is a sample line in the input:

Q

2: 3 747213 1664968 1691047 4095634 5535664

In this sample, page 2 has links to page 3, 747213, and so on. Note that links are not necessarily two-way.

The **popularity** of a page is determined by the number of pages in <u>the whole Wikipedia</u> graph that link to that specific page. (Same number as **Exercise D**)

The application also takes a list of page IDs as an input (also called a <u>league list</u>). The goal of the application is to calculate the rank of pages in the league using their popularity.

The <u>rank</u> of the page is the number of pages in the <u>league</u> with strictly less (not equal) popularity than the original page.

The following is the sample command we will use to run the application:

```
# hadoop jar /usr/local/hadoop/share/hadoop/tools/lib/hadoop-strea
ming-2.9.0.jar -mapper 'PopularityLeagueMapper.py
dataset/league.txt' -file PopularityLeagueMapper.py -reducer
'PopularityLeagueReducer.py' -file PopularityLeagueReducer.py
-input ./linkCount-output_Python -output ./E-output_Python
```

If you want to check your output, run:

```
1 # cat E-output_Python/part-00000
```

Here is the output with **League**={5300058,3294332,3078798,1804986,2370447,81615,3,1}):

Here is the output with **League**= {88822,774931,4861926,1650573,66877,5115901,75323,4189215}):

88822	/
774931	0
75323	5
66877	3
5115901	4
4861926	0
4189215	6
1650573	2

Q

The order matters. Please sort your output (key value) in decreasing alphabetic order. Also, make sure the key and value pair in final output are tab separated.

Note that we will use a different League file in our test.

How to submit

When you're ready to submit, you can upload files for each part of the assignment on the "My submission" tab.
